AB Xenogeneic DNA vaccination can elicit tumor immunity through T cell and antibody-dependent effector mechanisms. Blockade of CTLA-4 engagement with B7 expressed on APCs has been shown to enhance T cell-dependent immunity. We investigated whether CTLA-4 blockade could increase T-cell responses and tumor immunity elicited by DNA vaccines. CTLA-4 blockade enhanced B16 tumor rejection in mice immunized against the melanoma differentiation antigens tyrosinase-related protein 2 and gp100, and this effect was stronger when anti-CTLA-4 was administered with booster vaccinations. CTLA-4 blockade also increased the T-cell responses to prostate-specific membrane antigen (PSMA) when given with the second or third vaccination. Based on these pre-clin. studies, we suggest that anti-CTLA-4 should be tested with xenogeneic DNA vaccines against cancer and that special attention should be given to sequence and schedule of administration.

A review. The adaptive immune system is capable of recognizing cancer through T and B-cell receptors. However, priming adaptive immunity against self antigens is potentially a difficult task. Presentation of altered self to the immune system is a strategy to elicit immunity against poorly immunogenic antigens. We have shown that immunization with conserved paralogues of tumor antigens can induce adaptive immunity against self antigens expressed by cancer. Remarkably, cancer immunity elicited by closely related paralogues can generate distinct adaptive immune responses, either antibody or T-cell dependent. Cancer immunity induced by xenogeneic immunization follows multiple and alternative pathways. The effector phase of tumor immunity can be mediated by cytotoxic T cells or macrophages and perhaps natural killer cells for antibody-dependent immunity. Helper CD4+ T cells are typically, but not always, required to generate immunity. Autoimmunity is frequently observed following immunization. Cancer immunity and autoimmunity use overlapping mechanisms, and therefore they are difficult to uncouple, but distinct pathways can be discerned that open the eventual possibility of uncoupling tumor immunity from autoimmunity. Studies examining the mol.

basis for immunogenicity of conserved paralogues are facilitating the development of new strategies to rationally design vaccines that trigger adaptive immune responses to cancer.

Journal English LANGUAGE:

Successful active immunization against cancer requires induction of AB immunity against self or mutated self Ags. However, immunization against self Ags is difficult. Xenogeneic immunization with orthologous Ags induces cancer immunity. The present study evaluated the basis for immunity induced by active immunization against a melanoma differentiation Ag, gp100. Tumor rejection of melanoma was assessed after immunization with human gp100 (hgp100) DNA compared with mouse gp100 (mgp100). C57BL/6 mice immunized with xenogeneic full-length hgp100 DNA were protected against syngeneic melanoma challenge. In contrast, mice immunized with hgp100 DNA and given i.p. tolerizing doses of the hgp100 Db-restricted peptide, hgp10025-33, were incapable of rejecting tumors. Furthermore, mice immunized with DNA constructs of hgp100 in which the hgp10025-27 epitope was substituted with the weaker Db-binding epitope from mgp100 (mgp10025-27) or a mutated epitope unable to bind Db did not reject B16 melanoma. Mice

immunized with a minigene construct of hgp10025-33 rejected B16 melanoma, whereas mice immunized with the mgp10025-33 minigene did not develop protective tumor immunity. In this model of xenogeneic DNA immunization, the presence of an hgp100 heteroclitic epitope with a higher affinity for MHC created by three amino acid (25 to 27) substitutions at predicted minor anchor residues was necessary and sufficient to induce protective tumor immunity in H-2b mice with melanoma.

AB Canine malignant melanoma (CMM) is a spontaneous, aggressive, and metastatic neoplasm. Preclin. mouse studies have shown that

xenogeneic DNA vaccination with genes encoding tyrosinase family members can induce antibody and cytotoxic T-cell responses, resulting in tumor rejection. These studies provided the rationale for a trial of xenogeneic DNA vaccination in CMM using the human tyrosinase gene. Three cohorts of three dogs each with advanced (WHO stage II, III, or IV) CMM received four biweekly i.m. injections (dose levels 100, 500, or 1500 μg, resp./vaccination) of human tyrosinase plasmid DNA i.m. via the Biojector2000 delivery device. Mild local reactions at injection sites were the only toxicities observed, with no signs of autoimmunity. One dog with stage IV disease had a complete clin. response in multiple lung metastases for 329 days. Two dogs with stage IV disease had long-term survivals (421 and 588+ days) in the face of significant bulky metastatic disease, and two other dogs with locally controlled stage II/III disease had long-term survivals (501 and 496 days) with no evidence of melanoma on necropsy. Four other dogs were euthanized because of progression of the primary tumor. The Kaplan-Meier median survival time for all nine dogs was 389 days. The results of this trial demonstrate that xenogeneic DNA vaccination of dogs with advanced malignant ${f melanoma}$ is a safe and potentially therapeutic modality. On the basis of these results, addnl. evaluation of this novel therapeutic is warranted in locally controlled CMM and advanced human melanoma.

     Introduction. DNA immunization with xenogeneic genes encoding
AΒ
     homologous antigens protects mice against tumor challenge with syngeneic
     melanoma in a lung metastasis model. The effect of
     xenogeneic human TRP-2 (hTRP2) DNA immunization on disease
     confined to an orthotopic site, the skin, and in a model of minimal
     residual disease that is relevant to a setting of adjuvant therapy for
     micrometastatic cancer is reported. Methods. Immunization and tumor
     challenge with B16F10LM3 melanoma were performed in C57BL/6 mice
     and in mice genetically deficient in MHC class I or II mols. A
     melanoma variant of B16 with a predilection for lung metastasis
     was selected and used to challenge C57BL/6 mice. Tumor challenge in the
```

footpad with the B16 variant was followed by local tumor growth and lung metastasis. The tumor-bearing distal extremities were surgically resected

and mice were randomized to receive hTRP2 DNA immunization or no treatment. Approx. 3-5 wk after surgical resection, lungs were harvested and metastases counted. Results. **Xenogeneic** DNA immunization with hTRP2 prevented tumor growth in the skin by a mechanism requiring CD4+ and CD8+ T cells but did not inhibit the growth of established tumors. Adjuvant immunization with hTRP2 DNA after resection significantly reduced lung metastases and decreased local recurrence rates after surgical resection. Conclusions. **Xenogeneic** DNA immunization with hTRP2 was effective in protecting mice from intradermal tumor challenge. Immunization prevented local recurrence and the development of metastases in a mouse model of minimal residual disease, supporting a role for DNA immunization against melanosomal antigens as an adjuvant to surgery in high-risk primary **melanomas**. Xenogeneic DNA immunization with human TRP-2 (hTRP2) is capable AΒ of protecting mice against challenge with syngeneic melanoma. Immunol. therapy has not been as successful in the treatment of established tumors. One explanation is that the tumor induces tolerance and may prevent development of a cytotoxic T-cell response. An orthotopic model of mouse melanoma in which tumor burden is minimal, and spontaneous metastases occur in a predictable manner, has been developed. Immune response in this model may be more relevant to the clin. setting in which the primary tumor has been resected and the patient remains at high risk for the development of metastases. A study was conducted to determine whether DNA vaccination could prevent metastases in this model of minimal residual disease. The findings showed that xenogeneic DNA immunization with TRP-2 was effective in preventing the development of metastases in a mouse model of minimal residual disease. These results support a role for immunotherapeutic strategies as an adjuvant to surgery by demonstrating that an effective antitumor response is possible in the presence of micrometastases. In addition, this model provides a method for the preclin. assessment of antimetastatic tumor immunity.

We have shown previously that active immunization of mice against the melanocyte differentiation antigen, a tyrosinase-related protein (TRP) gp75TRP-1 (the brown locus protein) expressed by melanomas, could induce tumor immunity and autoimmunity manifested as depigmentation. In this system, tumor immunity and autoimmunity were mediated by autoantibodies. Here, we characterize immunity against another tyrosinase family glycoprotein TRP-2 (the slaty locus protein), using the same mouse model and method of immunization. As observed previously for gp75TRP-1, immunity was induced by DNA immunization against a xenogeneic form of TRP-2, but not against the syngeneic gene, and depended on CD4+ cells. Immunization against TRP-2 induced autoantibodies and autoreactive cytotoxic T cells. In contrast to immunization against gp75TRP-1, both tumor immunity and autoimmunity required CD8+ T cells, but not antibodies. Only autoimmunity required perforin, whereas tumor immunity proceeded in the absence of perforin. Thus, immunity induced against two closely related autoantiques that are highly conserved throughout vertebrate evolution involved qual. different mechanisms, i.e., antibody vs. CD8+ T cell. However, both pathways led to tumor immunity and identical phenotypic manifestations of autoimmunity. 15-8 (Immunochemistry) CC tumor immunity autoimmunity TRP2 gene immunization STGlycoproteins, specific or class ΙT RL: BAC (Biological activity or effector, except adverse); BSU (Biological study, unclassified); BIOL (Biological study) (TRP-2; tumor immunity and autoimmunity by DNA immunization with TRP-2 glycoprotein) IT Antibodies RL: BSU (Biological study, unclassified); MFM (Metabolic formation); BIOL (Biological study); FORM (Formation, nonpreparative) (autoantibodies; tumor immunity and autoimmunity by DNA immunization with TRP-2 glycoprotein) IT Immunity (autoimmunity; tumor immunity and autoimmunity by DNA immunization with TRP-2 glycoprotein)

LANGUAGE: Recognition of self is emerging as a theme for the immune recognition of human cancer. One question is whether the immune system can actively respond to normal tissue autoantigens expressed by cancer cells. A second but related question is whether immune recognition of tissue autoantigens can actually induce tumor rejection. To address these issues, a mouse model was developed to investigate immune responses to a melanocyte differentiation antigen, tyrosinase-related protein 1 (or gp75), which is the product of the brown locus. In mice, immunization with purified syngeneic gp75 or syngeneic cells expressing gp75 failed to elicit antibody or cytotoxic T-cell responses to gp75, even when different immune adjuvants and cytokines were included. However, immunization with altered sources of gp75 antigen, in the form of either syngeneic gp75 expressed in insect cells or human gp75, elicited autoantibodies to gp75. Immunized mice rejected metastatic melanomas and developed patchy depigmentation in their coats. These studies support a model of tolerance maintained to a melanocyte differentiation antigen where tolerance can be broken by presenting sources of altered antigen (e.g., homologous xenogeneic protein or protein expressed in insect cells). Immune responses induced with these sources of altered antigen reacted with various processed forms of native, syngeneic protein and could induce both tumor rejection and autoimmunity.
